

## Safety recommendation no. 11

Date of the publication	04.10.2018
Number of the final report	2283
Safety deficit	<ul> <li>On 27 April 2015, approximately 300 m north of the Zweisimmen Airfield (LSTZ), the Comco Ikarus C 42, registered as HB-WAS, collided with the terrain due to a loss of engine power experienced during a simulated engine failure involving a 180° turn at too low a height.</li> <li>The accident happened during an annual proficiency check that was compulsory within the flying club. On board of the aircraft were a pilo and a flight instructor, who sustained serious and minor injuries respectively. The aircraft was destroyed.</li> <li>As part of the investigation, it was ascertained that the manufacturer had published the following recommendation in the emergency procedures section of the aircraft flight manual (AFM) of HB-WAS regarding the topic of 180° turns following an engine failure during a take-off:</li> <li>"3.2.1.2. Engine failure during take-off</li> <li>Depending on the speed and flying altitude (should be height!), immediately move the control stick forward, maintain the glide speed (90-100 km/h) and flare the aircraft normally.</li> <li>For 180° turns, a minimum height of approximately 80 m is required after establishing the gliding flight position. Below this height, land in a straight-ahead direction or straight-ahead with minor directional changes."</li> </ul>
Safety recommendation	Topic: Emergency procedures with regards to the Comco Ikarus C 42; engine failure after take-off Target group: General aviation pilots and flight instructors, manufacturers, flight schools and the Federal Office of Civil Aviation (FOCA)
	The recommendation from the manufacturer stands in salient opposition to the generally known recommendations in current teaching materials provided by well-known aviation organisations in Switzerland. Furthermore, the manufacturer does not provide information regarding the conditions under which such a 180° turn could be flown. In this accident, the 180° turn was initiated at a height considerably higher than the stated minimum, but still did not allow the crew to find a suitable spot for an emergency landing. This shows that, in order to determine a decision height, an analysis of factors relevant to the situation such as runway, obstacles, topography, wind, aircraft mass, etc. has to take place before the take-off. In particular, the operators of this type of aircraft should raise awareness among their pilots regarding this and make the consequential potential risks a subject of discussion.
